***Abstract*—Low-density parity-check (LDPC) convolutional codes (or spatially-coupled codes) have been shown to approach capacity on the binary erasure channel (BEC) and binary-input memoryless symmetric channels. The mechanism behind this spectacular performance is the threshold saturation phenomenon, which is characterized by the belief-propagation threshold of the spatially-coupled ensemble increasing to an intrinsic noise threshold defined by the uncoupled system.**

In this paper, we present a simple proof of threshold saturation that applies to a broad class of coupled scalar recursions. The conditions of the theorem are verified for the density-evolution (DE) equations of irregular LDPC codes on the BEC, a class of generalized LDPC codes, and the joint iterative decoding of LDPC codes on intersymbol-interference channels with erasure noise. Our approach is based on potential functions and was motivated mainly by the ideas of Takeuchi et al. The resulting proof is surprisingly simple when compared to previous methods.

***Index Terms*—convolutional LDPC codes, spatial coupling, threshold saturation, density evolution, potential functions**

I. INTRODUCTION

Convolutional low-density parity-check (LDPC) codes, or spatially-coupled (SC) LDPC codes, were introduced in [1] and shown to have excellent belief-propagation (BP) thresholds in [2], [3], [4]. Moreover, they have recently been observed to *universally* approach the capacity of various channels [4], [5], [6], [7], [8], [9], [10], [11].

The fundamental mechanism behind this is explained well in [12], where it is proven analytically for the BEC that the BP threshold of a particular SC ensemble converges to the maximum-a-posteriori (MAP) threshold of the underlying ensemble. This phenomenon is now called *threshold saturation*. A similar result was also observed independently in [13] and stated as a conjecture. The same result for general binary memoryless symmetric (BMS) channels was first empirically observed [4], [5] and recently proven analytically [11].

The underlying principle behind threshold saturation appears to be very general and it has now been applied, with much success, to a variety of more general scenarios in information theory and coding. In [14], the benefits of spatial coupling are described for K-satisfiability, graph coloring, and the Curie-Weiss model in statistical physics. SC codes are shown to achieve the entire rate-equivocation region for the BEC wiretap channel in [6]. The authors observe in [7] that the phenomenon of threshold saturation extends to multi-terminal problems (e.g., a noisy Slepian-Wolf problem) and can provide universality over unknown channel parameters. Threshold saturation has also been observed for the binary-adder channel [15], for intersymbol-interference channels [8], [9], [10], for message-passing decoding of code-division multiple access (CDMA) [16], [17], and for iterative hard-decision decoding of SC generalized LDPC codes [18]. For compressive sensing, SC measurement matrices were investigated first with verification-based reconstruction in [19], and then proved to achieve the information-theoretic limit in [20].

In many of these papers it is conjectured, either implicitly or explicitly, that threshold saturation occurs for the studied problem. A general proof of threshold saturation (especially one where only a few details must be verified for each system) would allow one to settle all of these conjectures simultaneously. In this paper, we provide such a proof for systems with scalar density-evolution (DE) equations.

Our method is based on potential functions and was motivated mainly by the approach taken in [21]. It turns out that their approach is missing a few important elements and does not, as far as we know, lead to a general proof of threshold saturation. Still, it introduces the idea of a potential function defined by an integral of the DE recursion and this is an important element in our approach. More recently, a continuum approach to DE is used, in [20], to prove threshold saturation for compressed sensing and was reported informally to give a general proof [22].

II. A SIMPLE PROOF OF THRESHOLD SATURATION

In this section, we provide a simple proof of threshold saturation via spatial-coupling for a broad class of scalar recursions. The main tool is a potential theory for scalar recursions that extends naturally to coupled systems of recursions.

A. Single-System Potential

First, we define potential functions for a class of scalar recursions and discuss threshold parameters associated with the potential.

Definition 1: An *scalar admissible system* (f, g) parameterized by $\varepsilon \in [0,1]$, is defined by the recursion

$$x^{(\ell+1)} = f(g(x^{(\ell)}); \varepsilon), \tag{1}$$

where $f : [0,1] \times [0,1] \to [0,1]$ is strictly increasing in both arguments for $x, \varepsilon \in (0,1]$, and $g : [0,1] \to [0,1]$

This material is based upon work supported by the National Science Foundation (NSF) under Grants No. 0747470 and No. 0802124. Any opinions, findings, conclusions, and recommendations expressed in this material are those of the authors and do not necessarily reflect the views of these sponsors.

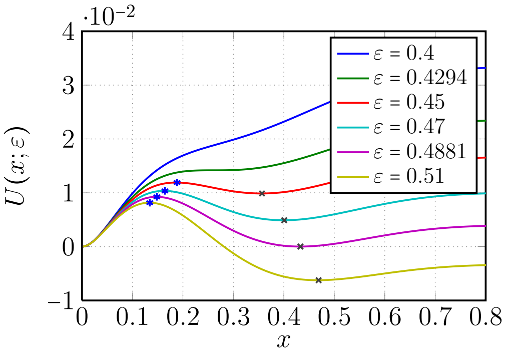

Figure 1. The potential function of the (3,6)-regular LDPC ensemble is shown for a range of ε. Here $\varepsilon_s^* \approx 0.4294$, $\varepsilon^* \approx 0.4881$, and the stationary points are marked. Notice that, for $\varepsilon < \varepsilon_s^*$, $U(x;\varepsilon)$ has no stationary points.

satisfies $g'(x) > 0$ for $x \in (0,1)$. We also assume that $f(0;\varepsilon) = f(x;0) = g(0) = 0$ and that f, g have continuous second derivatives on $[0,1]$ w.r.t. all arguments.

Definition 2: The *potential function* $U(x;\varepsilon)$ of a scalar admissible system (f,g) is defined by

$$\begin{aligned} U(x;\varepsilon) &\triangleq \int_0^x (z - f(g(z);\varepsilon))\, g'(z)\mathrm{d}z \\ &= xg(x) - G(x) - F(g(x);\varepsilon), \end{aligned} \tag{2}$$

where $F(x;\varepsilon) = \int_0^x f(z;\varepsilon)\mathrm{d}z$ and $G(x) = \int_0^x g(z)\mathrm{d}z$.

Definition 3: For $x, \varepsilon \in [0,1]$, we have the following terms.

- For fixed ε, x is a *fixed point* (f.p.) iff $x = f(g(x);\varepsilon)$.
- For fixed ε, x is a *stationary point* (s.p.) if $U'(x;\varepsilon) = 0$.
- For $0 < x \le f(g(x);1)$, we define $\varepsilon(x)$ to be the unique ε*-root* of the equation $x - f(g(x);\varepsilon) = 0$.

Lemma 1: The potential function of a scalar admissible system has the following properties:

1) $U(x;\varepsilon)$ is strictly decreasing in ε, for $\varepsilon \in (0,1]$.
2) An $x \in [0,1]$ is a f.p. iff it is a s.p. of the potential.

Proof: These properties hold because the potential function is the integral of $(z - f(g(z);\varepsilon))\, g'(z)$ w.r.t. z, which is strictly decreasing in ε, for $\varepsilon \in (0,1]$, and zero iff z is a fixed point of the recursion. ■

Definition 4: The *single-system threshold* is defined to be

$$\varepsilon_s^* = \sup\left\{\varepsilon \in [0,1] \mid U'(x;\varepsilon) > 0\ \forall\ x \in (0,1]\right\},$$

and is the ε-threshold for convergence of the single-system recursion to 0. It is well defined because $U'(x;\varepsilon)$ is strictly decreasing in ε. This implies that, for $\varepsilon < \varepsilon_s^*$, (1) has no fixed points in $(0,1]$. For DE recursions associated with BP decoding, the threshold ε_s^* is called the BP threshold.

Example 1: For the standard irregular ensemble of LDPC codes (e.g., see [23]), the DE recursion,

$$x^{(\ell+1)} = \varepsilon\lambda(1 - \rho(1 - x^{(\ell)})),$$

is an scalar admissible system with $f(x;\varepsilon) = \varepsilon\lambda(x)$ and $g(x) = 1 - \rho(1-x)$. In this case, the single-system potential is given by (6) and is shown in Fig. 1 for the $(3,6)$-regular LDPC code ensemble defined by $(\lambda, \rho) = (x^2, x^5)$.

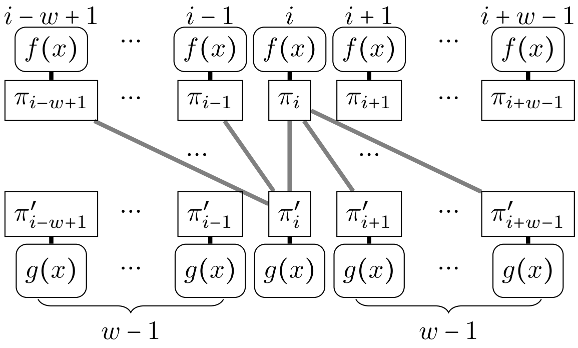

Figure 2. A portion of a generic SC system. The f-node at position i is coupled with the g-nodes at positions $i, \ldots, i+w-1$ and, by reciprocity, g-node at position i is coupled with the f-nodes at positions $i-w+1, \ldots, i$. Here, π_i and π'_i are random permutations.

Definition 5: For $\varepsilon > \varepsilon_s^*$, we define the *minimum unstable* fixed point to be

$$u(\varepsilon) = \sup\{\tilde{x} \in [0,1] \mid U'(x;\varepsilon) \ge 0, x \in [0, \tilde{x}]\}.$$

Definition 6: Let the *potential threshold* of the system be

$$\varepsilon^* = \sup\{\varepsilon \in [0,1] \mid \min_{x \in [0,1]} U(x;\varepsilon) \ge 0\} \tag{3}$$

and $\Delta E(\varepsilon) = \min_{x \in [u(\varepsilon),1]} U(x;\varepsilon)$ be the *energy gap* of the system for $\varepsilon \in (\varepsilon_s^*, 1]$.

Remark 1: One consequence of this definition is that, if $\varepsilon < \varepsilon^*$, then $U(x;\varepsilon) > 0$ for $x \in (0,1]$. Likewise, if $\Delta E(\varepsilon) = 0$, then $\varepsilon = \varepsilon^*$. For DE recursions associated with BP decoding, the potential threshold is analogous to the threshold predicted by the Maxwell conjecture [24, Conj. 1].

B. Coupled System Potential

Now, we extend our definition of potential functions to coupled systems of scalar recursions. In particular, we consider a “spatial-coupling” of the single-system recursion, (1), that gives rise to the vector recursion (4). For the vector recursion of the coupled system, we define a potential function and show that, for $\varepsilon < \varepsilon^*$, the only fixed point of the coupled system is the zero vector.

Definition 7 (cf. [12]): The basic *spatially-coupled system* is defined by placing $2L+1$ single systems at positions in the set $\mathcal{L}_0 \triangleq \{-L, -L+1, \ldots, L\}$ and coupling them with w systems as shown in Fig. 2. Let $x_i^{(\ell)}$ be the input to the g-function in the i-th position after ℓ iterations and define $x_i^{(\ell)} = 0$ for $i \notin \mathcal{L} \triangleq \{-L, -L+1, \ldots, L+w-1\}$ and all ℓ. For the coupled system, we have the recursion

$$x_i^{(\ell+1)} = \frac{1}{w}\sum_{k=0}^{w-1} f\left(\frac{1}{w}\sum_{j=0}^{w-1} g(x_{i+j-k}^{(\ell)}); \varepsilon_{i-k}\right), \tag{4}$$

where $\varepsilon_i = \varepsilon$ for $i \in \mathcal{L}_0$ and $\varepsilon_i = 0$ for $i \notin \mathcal{L}_0$.

Definition 8: The recursion defined by (4) can be rewritten as a *vector recursion*. Let $\boldsymbol{f}(\boldsymbol{x};\varepsilon)$ and $\boldsymbol{g}(\boldsymbol{x})$ be defined for vector arguments by $[\boldsymbol{f}(\boldsymbol{x};\varepsilon)]_i = f(x_i;\varepsilon)$ and $[\boldsymbol{g}(\boldsymbol{x})]_i = g(x_i)$, respectively. Then, (4) is equivalent to

$$\boldsymbol{x}^{(\ell+1)} = \boldsymbol{A}_2^{\intercal}\boldsymbol{f}(\boldsymbol{A}_2\boldsymbol{g}(\boldsymbol{x}^{(\ell)});\varepsilon),$$

where $\boldsymbol{A}_2$ is the $(2L+1) \times (2L+w)$ matrix given by

$$\boldsymbol{A}_2 = \frac{1}{w}\left.\left[\;\underbrace{\begin{array}{cccccccc} \multicolumn{4}{c}{\overbrace{1 \quad 1 \quad \cdots \quad 1}^{w}} & 0 & 0 & \cdots & 0 \\ 0 & 1 & 1 & \cdots & 1 & 0 & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & 1 & 1 & \cdots & 1 & 0 \\ 0 & \cdots & 0 & 0 & 1 & 1 & \cdots & 1 \end{array}}_{2L+w}\;\right]\right\} 2L+1$$

Remark 2: In contrast to [12], the SC recursion defines $\boldsymbol{x}^{(\ell)}$ to be the *SC-average* of the f-function (e.g., bit node in the LDPC example) output values rather than the output values. Since there are $2L+1$ active f-function outputs, the vector $\boldsymbol{x}^{(\ell)}$ contains the $2L+w$ active averaged values after convolution with the length-w averaging sequence. This also shifts the maximum value of the vector from position 0, in [12], to position $i_0 \triangleq \left\lfloor \frac{w-1}{2} \right\rfloor$ in this work.

One might also expect that A_2 is square and that all rows and columns should sum to 1, but the termination leads to a rectangular matrix with reduced column sums near the boundaries. In particular, $\boldsymbol{A}_2\boldsymbol{g}(\boldsymbol{x})$ is a length $2L+1$ vector representing the inputs to the $2L+1$ active f-functions.

Definition 9 (cf. [12]): The *one-sided spatially-coupled system* is a modification of (4) defined by fixing the values of positions outside $\mathcal{L}' \triangleq \{-L, L+1, \ldots, i_0\}$, where $i_0 = \left\lfloor \frac{w-1}{2} \right\rfloor$ is the position of the maximum element of $\boldsymbol{x}^{(\ell)}$. It fixes the left boundary to zero by defining $x_i^{(\ell)} = 0$ for $i < -L$ and all ℓ. It forces the right boundary to a floating constant by setting $x_i^{(\ell)} = x_{i_0}^{(\ell)}$ for $i \geq i_0$ and all ℓ.

Definition 10: Let the *vector one-sided SC recursion* be

$$\boldsymbol{x}^{(\ell+1)} = \boldsymbol{A}^{\top}\boldsymbol{f}(\boldsymbol{A}\boldsymbol{g}(\boldsymbol{x}^{(\ell)});\varepsilon), \tag{5}$$

where $\boldsymbol{x}^{(\ell)} = [x_{-L-w}^{(\ell)}, \ldots, x_{2w+i_0}^{(\ell)}]$ and $\boldsymbol{A}$ is the $(L+3w+i_0+1) \times (L+3w+i_0+1)$ matrix given by

$$\boldsymbol{A} = \frac{1}{w}\begin{bmatrix} 1 & 1 & \cdots & 1 & 0 & \cdots & 0 \\ 0 & 1 & 1 & \cdots & 1 & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & 0 \\ 0 & \cdots & 0 & 1 & 1 & \cdots & 1 \\ 0 & 0 & \cdots & 0 & 1 & \ddots & 1 \\ 0 & 0 & \cdots & 0 & 0 & 1 & \vdots \\ 0 & 0 & \cdots & 0 & 0 & 0 & 1 \end{bmatrix}.$$

Remark 3: The right hand side of (5) accurately represents a single iteration of the one-sided SC system update for $i \in \mathcal{L}'$, but cannot be used recursively unless the boundary condition $x_i^{(\ell)} = x_{i_0}^{(\ell)}$ for $i \geq i_0$ is enforced after each step.

Lemma 2 (cf. [12, Lem. 14]): For both the basic and one-sided SC systems, the recursions are component-wise decreasing with iteration and converge to well-defined fixed points. The one-sided recursion is also a component-wise upper bound on the basic SC recursion for $i \in \mathcal{L}$ and it converges to a non-decreasing fixed-point vector.

Proof: The proof follows easily from the arguments in [12, Sec. V] and is, hence, omitted. ■

Definition 11: The *coupled-system potential* can be computed for general vector recursions written in the form of (5). Integrating a scaled version of the vector update step along a curve $\mathcal{C}$, from $\mathbf{0}$ to $\boldsymbol{x}$, gives the potential function

$$\begin{aligned} U(\boldsymbol{x};\varepsilon) &= \int_{\mathcal{C}} \boldsymbol{g}'(\boldsymbol{z})(\boldsymbol{z} - \boldsymbol{A}^{\top}\boldsymbol{f}(\boldsymbol{A}\boldsymbol{g}(\boldsymbol{z});\varepsilon)) \cdot \mathrm{d}\boldsymbol{z} \\ &= \boldsymbol{g}(\boldsymbol{x})^{\top}\boldsymbol{x} - G(\boldsymbol{x}) - F(\boldsymbol{A}\boldsymbol{g}(\boldsymbol{x});\varepsilon), \end{aligned}$$

where $\boldsymbol{g}'(\boldsymbol{x}) = \mathrm{diag}([g'(x_i)])$, $G(\boldsymbol{x}) = \int_{\mathcal{C}} \boldsymbol{g}(\boldsymbol{z}) \cdot \mathrm{d}\boldsymbol{z} = \sum_i G(x_i)$ and $F(\boldsymbol{x};\varepsilon) = \int_{\mathcal{C}} \boldsymbol{f}(\boldsymbol{z};\varepsilon) \cdot \mathrm{d}\boldsymbol{z} = \sum_i F(x_i;\varepsilon)$.

Remark 4: A key observation in this paper is that a potential function for coupled systems can be written in the simple form in Def. 11. Remarkably, this holds for general coupling coefficients because of the $\boldsymbol{A}, \boldsymbol{A}^{\top}$ reciprocity that appears naturally in SC.

Lemma 3: Let $\boldsymbol{x} \in [0,1]^n$ be a non-decreasing vector generated by averaging $\boldsymbol{z} \in [0,1]^n$ over a sliding window of size w. Let the shift operator $\boldsymbol{S} : \mathbb{R}^n \to \mathbb{R}^n$ be defined by $[\boldsymbol{S}\boldsymbol{x}]_1 = 0$ and $[\boldsymbol{S}\boldsymbol{x}]_i = x_{i-1}$ for $i \geq 2$. Then, one can show $\|\boldsymbol{S}\boldsymbol{x} - \boldsymbol{x}\|_\infty \leq \frac{1}{w}$ and $\|\boldsymbol{S}\boldsymbol{x} - \boldsymbol{x}\|_1 = x_n = \|\boldsymbol{x}\|_\infty$.

Proof: The bound $\|\boldsymbol{S}\boldsymbol{x} - \boldsymbol{x}\|_\infty \leq \frac{1}{w}$ follows from

$$x_i - x_{i-1} = \tfrac{1}{w}\textstyle\sum_{j=0}^{w-1} z_{i-j} - \tfrac{1}{w}\sum_{j=0}^{w-1} z_{i-1-j} \leq \tfrac{1}{w},$$

where $z_i = 0$ for all $i < 0$. Since $\boldsymbol{x}$ is non-decreasing, the 1-norm sum telescopes and we get $\|\boldsymbol{S}\boldsymbol{x} - \boldsymbol{x}\|_1 = |0 - x_1| + \sum_{i=2}^{n} |x_{i-1} - x_i| = x_n = \|\boldsymbol{x}\|_\infty$. ■

Lemma 4: For the vector one-sided SC system, a shift changes the potential by $U(\boldsymbol{S}\boldsymbol{x};\varepsilon) - U(\boldsymbol{x};\varepsilon) = -U(x_{i_0};\varepsilon)$.

Sketch of Proof: First, we rewrite the potential as the summation

$$U(\boldsymbol{x};\varepsilon) = \textstyle\sum_{i=-L-w}^{2w+i_0} \left[g(x_i)x_i - G(x_i) - F\left([\boldsymbol{A}\boldsymbol{g}(\boldsymbol{x})]_i;\varepsilon\right)\right].$$

One can verify that the contribution, from the first two terms in the square brackets, to $U(\boldsymbol{S}\boldsymbol{x};\varepsilon) - U(\boldsymbol{x};\varepsilon)$ is a telescoping sum that leaves only the difference between the first and last values. For the third term in the square brackets, more care is required. Since the first w values of $\boldsymbol{x}$ are 0 and the last $2w+1$ values of $\boldsymbol{x}$ equal x_{i_0}, it can be shown that $\sum_{i=-L-w}^{2w+i_0} F\left([\boldsymbol{A}\boldsymbol{g}(\boldsymbol{S}\boldsymbol{x})]_i;\varepsilon\right) - F\left([\boldsymbol{A}\boldsymbol{g}(\boldsymbol{x})]_i;\varepsilon\right) = F(g(0);\varepsilon) - F\left(g(x_{i_0});\varepsilon\right)$. Thus, we have

$$U(\boldsymbol{S}\boldsymbol{x};\varepsilon) - U(\boldsymbol{x};\varepsilon) = -U(x_{i_0};\varepsilon).$$ ■

Lemma 5: For the SC potential, the norm of the Hessian $U''(\boldsymbol{x};\varepsilon)$ is independent of L and w and satisfies

$$\|U''(\boldsymbol{x};\varepsilon)\|_\infty \leq K_{f,g} \triangleq \|g'\|_\infty + \|g'\|_\infty^2 \|f'\|_\infty + \|g''\|_\infty,$$

where $\|h\|_\infty = \sup_{x\in[0,1]} |h(x)|$ for functions $h : [0,1] \to \mathbb{R}$.

Proof: One can verify that the Hessian is given by

$$\begin{aligned} U''(\boldsymbol{x};\varepsilon) = {}& \boldsymbol{g}'(\boldsymbol{x}) - (\boldsymbol{A}\boldsymbol{g}'(\boldsymbol{x}))^{\top}\boldsymbol{f}'(\boldsymbol{A}\boldsymbol{g}(\boldsymbol{x});\varepsilon)\boldsymbol{A}\boldsymbol{g}'(\boldsymbol{x}) \\ & + \boldsymbol{g}''(\boldsymbol{x})\mathrm{diag}\left(\boldsymbol{x} - \boldsymbol{A}^{\top}\boldsymbol{f}(\boldsymbol{A}\boldsymbol{g}(\boldsymbol{x});\varepsilon)\right), \end{aligned}$$

where $\boldsymbol{g}''(\boldsymbol{x}) = \mathrm{diag}([g''(x_i)])$. Taking the norm gives

$$\begin{aligned} \|U''(\boldsymbol{x};\varepsilon)\|_\infty \leq {}& \|\boldsymbol{g}'(\boldsymbol{x})\|_\infty + \|\boldsymbol{A}\boldsymbol{g}'(\boldsymbol{x}))\|_1 \left\|\boldsymbol{f}'(\boldsymbol{A}\boldsymbol{g}(\boldsymbol{x});\varepsilon)\right\|_\infty \\ & \cdot \|\boldsymbol{A}\boldsymbol{g}'(\boldsymbol{x}))\|_\infty + \left\|\boldsymbol{g}''(\boldsymbol{x})\mathrm{diag}\left(\boldsymbol{x} - \boldsymbol{A}^{\top}\boldsymbol{f}(\boldsymbol{A}\boldsymbol{g}(\boldsymbol{x});\varepsilon)\right)\right\|_\infty. \end{aligned}$$

Since $\|\boldsymbol{A}\|_\infty = \|\boldsymbol{A}\|_1 = 1$ and $\|\boldsymbol{g}'(\boldsymbol{x})\|_\infty = \|\boldsymbol{g}'(\boldsymbol{x})\|_1 \leq \|g'\|_\infty$, we find that $\|U''(\boldsymbol{x};\varepsilon)\|_\infty \leq \|g'\|_\infty + \|g'\|_\infty^2 \|f'\|_\infty + \|g''\|_\infty$. ■

We now state the main result of the paper. Roughly speaking, it says that, if $\varepsilon < \varepsilon^*$ and w is sufficiently large, then one can always lower the coupled potential of a non-zero vector by shifting. Since this implies the next step of the recursion must reduce some value, the only fixed point is the zero vector.

Theorem 1: Consider a scalar admissible system (f, g). If $\varepsilon < \varepsilon^*$ and $w > K_{f,g}/\Delta E(\varepsilon)$, then the only fixed point of the spatially-coupled system, defined by (4), is $\boldsymbol{x} = \boldsymbol{0}$.

Proof: Using Lem. 2, let $\boldsymbol{x}$ be the unique fixed point of the one-sided recursion defined in Def. 9. This fixed point upper bounds the fixed point of the basic SC system defined in Def. 7. If $\boldsymbol{x} \neq 0$, then $x_{i_0} \geq u(\varepsilon)$ because the system has no fixed points with $x_i < u(\varepsilon)$ for all i. From Lem. 4, we have $\Delta U \triangleq U(\boldsymbol{S}\boldsymbol{x};\varepsilon) - U(\boldsymbol{x};\varepsilon) = -U(x_{i_0};\varepsilon)$. Expanding $U(\boldsymbol{S}\boldsymbol{x};\varepsilon)$ in a Taylor series (with remainder) around $U(\boldsymbol{x};\varepsilon)$ gives

$$
\begin{aligned}
U'(\boldsymbol{x};\varepsilon)\cdot(\boldsymbol{S}\boldsymbol{x}-\boldsymbol{x}) &= U(\boldsymbol{S}\boldsymbol{x};\varepsilon) - U(\boldsymbol{x};\varepsilon) \\
&\quad - \int_0^1 (1-t)(\boldsymbol{S}\boldsymbol{x}-\boldsymbol{x})^\top U''(\boldsymbol{x}(t);\varepsilon)(\boldsymbol{S}\boldsymbol{x}-\boldsymbol{x})\mathrm{d}t \\
&\leq \Delta U + \left| \int_0^1 (1-t)(\boldsymbol{S}\boldsymbol{x}-\boldsymbol{x})^\top U''(\boldsymbol{x}(t);\varepsilon)(\boldsymbol{S}\boldsymbol{x}-\boldsymbol{x})\mathrm{d}t \right| \\
&\leq \Delta U + \|\boldsymbol{S}\boldsymbol{x}-\boldsymbol{x}\|_1 \max_{t\in[0,1]} \|U''(\boldsymbol{x}(t);\varepsilon)\|_\infty \|\boldsymbol{S}\boldsymbol{x}-\boldsymbol{x}\|_\infty \\
&\leq -U(x_{i_0};\varepsilon) + \tfrac{1}{w} x_{i_0} \max_{t\in[0,1]} \|U''(\boldsymbol{x}(t);\varepsilon)\|_\infty \\
&\leq -U(x_{i_0};\varepsilon) + \tfrac{1}{w} K_{f,g} \\
&< -U(x_{i_0};\varepsilon) + \Delta E(\varepsilon) \leq 0,
\end{aligned}
$$

where the last steps hold because $w > K_{f,g}/\Delta E(\varepsilon)$, $x_{i_0} \leq 1$, and $U(x;\varepsilon) \geq \Delta E(\varepsilon)$ for $x \geq u(\varepsilon)$.

Now, we observe that $\boldsymbol{S}\boldsymbol{x} - \boldsymbol{x} \preceq \boldsymbol{0}$ (i.e., the fixed point is non-decreasing) and $[\boldsymbol{S}\boldsymbol{x} - \boldsymbol{x}]_i$ is zero for $i \notin \mathcal{L}'$. So, $U'(\boldsymbol{x};\varepsilon)$ is positive in at least one component (i.e., there exists $i \in \mathcal{L}'$ such that $[U'(\boldsymbol{x};\varepsilon)]_i > 0$). Since $g'(x) \geq 0$ and $[U'(\boldsymbol{x};\varepsilon)]_i = g'(x_i)[\boldsymbol{x} - \boldsymbol{A}^\top f(\boldsymbol{A}g(\boldsymbol{x});\varepsilon)]_i$, it follows that $g'(x_i) > 0$ and $[\boldsymbol{A}^\top f(\boldsymbol{A}g(\boldsymbol{x});\varepsilon)]_i < x_i$. So, one more iteration must reduce the value of the i-th component for some $i \in \mathcal{L}'$. This gives a contradiction and shows that the only fixed point of the one-sided SC system is $\boldsymbol{x} = \boldsymbol{0}$. The result follows since the fixed point of the basic SC system is upper bounded by this f.p. ■

III. APPLICATIONS

In this section, we consider some applications of Theorem 1 for coding problems that are characterized by a scalar recursion. We liberally use notation and definitions from [23].

A. Irregular LDPC Codes

Consider the ensemble LDPC(λ, ρ) and transmission over an erasure channel with parameter ε. Let $x^{(\ell)}$ be the fraction of erasure messages sent from variable to check nodes during iteration ℓ. The DE equation can be written in the form of (1), where $f(x;\varepsilon) = \varepsilon\lambda(x)$ and $g(x) = 1 - \rho(1-x)$. It is easy to verify that f and g describe a scalar admissible system if $\lambda(0) = 0$. The single system potential is given by

$$U(x;\varepsilon) = \tfrac{1}{L'(1)}\left(-P(x) + (\varepsilon(x) - \varepsilon)L(1-\rho(1-x))\right), \quad (6)$$

where $P(x)$ is the trial entropy defined in [23, Def. 3.119], $\varepsilon(x) = x/\lambda(1-\rho(1-x))$ and $L(x) = \int_0^x \lambda(y)\mathrm{d}y / \int_0^1 \lambda(y)\mathrm{d}y$. In this case, the potential $U(x;\varepsilon)$ is the same as the pseudo-dual of the Bethe variational entropy in [25, Part 2, pp. 62-65].

Lemma 6: Consider the potential threshold ε^* given by (3). Let ε^{Max} be the Maxwell threshold [24, Conj. 1], defined by

$$\varepsilon^{\text{Max}} = \min\left\{\varepsilon(x) \,|\, P(x) = 0, x \in [0,1]\right\}. \quad (7)$$

Then, $\varepsilon^* = \varepsilon^{\text{Max}}$ for the ensemble LDPC(λ, ρ).

Sketch of Proof: Let x^{Max} be the x-value that achieves the minimum. Then, (6) and (7) imply $U(x^{\text{Max}};\varepsilon^{\text{Max}}) = U(x^{\text{Max}};\varepsilon(x^{\text{Max}})) = -P(x^{\text{Max}})/L'(1) = 0$. One can show $\Delta E(\varepsilon^{\text{Max}}) = U(x^{\text{Max}};\varepsilon^{\text{Max}}) = 0$, which implies $\varepsilon^* = \varepsilon^{\text{Max}}$. ■

Remark 5: For regular ensembles, ε^{Max} equals the MAP threshold ε^{MAP} and this is conjectured to hold in general.

Consider an SC ensemble of irregular LDPC(Λ, P) codes defined as follows. The f-nodes at each position are replaced by M copies of the node degree profile $\Lambda(x) = \sum_i \Lambda_i x^i$, where Λ_i is the number of bit nodes of degree i. The g-nodes at each position are replaced by M copies of the node degree profile $P(x) = \sum_i P_i x^i$, where P_i is the number of check nodes of degree i. For sufficiently large M, these nodes can be coupled uniformly using an averaging window of length w (see Fig. 2) in a manner similar to the $(\mathtt{l}, \mathtt{r}, L, w)$ ensemble defined in [12].

Corollary 1: Applying Theorem 1 shows that, if $\varepsilon < \varepsilon^{\text{Max}}$ and $w > K_{f,g}/\Delta E(\varepsilon)$, then the SC DE recursion converges to the zero vector.

B. Generalized LDPC Codes on the BEC and BSC

Consider a generalized LDPC (GLDPC) code with degree-2 bits and generalized check constraints based on a BCH code of block-length n. For iterative decoding using bounded-distance decoding of the BCH code, the DE recursions can be derived for both the BEC and binary symmetric channel (BSC) [18]. On the BEC, the code is chosen to correct all patterns of at most t erasures and, on the BSC, the code is chosen to correct all error patterns of weight at most t.

For both cases, the iterative decoding performance of this ensemble is characterized by a DE recursion of the form (1), where ε denotes the channel parameter. In this case, the scalar system is defined by $f(x;\varepsilon) \triangleq \varepsilon x$ and $g(x) \triangleq \sum_{e=t}^{n-1} \binom{n-1}{e} x^e (1-x)^{n-1-e}$. Here, x denotes the erasure (resp. error) probability of bit-to-check messages for the BEC (resp. BSC) case.

It can be verified that f and g define a scalar admissible system whose single-system potential is given by $U(x;\varepsilon) = \frac{1}{2}\left(-P(x) + g(x)(x - f(g(x);\varepsilon))\right)$, where

$$P(x) = \textstyle\int_0^x (g(z))^2 \varepsilon'(z)\mathrm{d}z = -xg(x) + 2\int_0^x g(z)\mathrm{d}z$$

is the analogous to the trial entropy defined in [23].

Lemma 7: For $2 \leq t \leq \lfloor \frac{n-1}{2} \rfloor$ on the BEC, $P(x)$ has an unique root, $\bar{x}$, in $(0, 1]$. Let $\bar{\varepsilon} \triangleq \varepsilon(\bar{x})$ be the ε-root, and ε^* be the potential threshold defined by (3). Then, $\varepsilon^* = \bar{\varepsilon}$ for the GLDPC ensemble.

Remark 6: Since this decoder uses suboptimal component decoders, the threshold defined by the unique zero of $P(x)$ does not give an upper bound on the MAP threshold.

We now describe the SC ensemble for the ensemble of GLDPC codes. The f-nodes in Fig. 2 are replaced by Mn degree-2 variable nodes and the g-nodes are replaced by $2M$ BCH codes of block-length n. These nodes are coupled using an averaging window of length w in a manner similar to the $(\mathtt{l}, \mathtt{r}, L, w)$ ensemble defined in [12] (e.g., see [18]).

Corollary 2: Applying Theorem 1 to this SC GLDPC ensemble shows that the SC DE recursion converges to the zero vector whenever $\varepsilon < \bar{\varepsilon}$ and $w > K_{f,g}/\Delta E(\varepsilon)$.

C. Intersymbol-Interference Channels with Erasure Noise

In [26], a family of intersymbol-interference (ISI) channels with erasure noise is investigated as an analytically tractable model of joint iterative decoding of LDPC codes and channels with memory. Let $\psi(t;\varepsilon)$ be the function that maps the *a priori* erasure rate t from the code and the channel erasure rate ε to the erasure rate of extrinsic messages from the channel detector to the bit nodes. Then, the resulting DE update equation for the erasure rate, $x^{(\ell)}$, of bit-to-check messages can be written in the form of (1), where $f(x;\varepsilon) = \psi(L(x);\varepsilon)\lambda(x)$ and $g(x) = 1 - \rho(1-x)$ [26]. This defines a scalar admissible system with potential

$$U(x;\varepsilon) = \tfrac{1}{L'(1)}\Psi(L(g(x));\varepsilon(x)) - \Psi(L(g(x));\varepsilon) - P(x),$$

where $\varepsilon(x)$ and $P(x)$ are defined in [9] for generalized erasure channels and $\Psi(x;\varepsilon) = \int_0^x \psi(y;\varepsilon)\mathrm{d}y$.

Lemma 8: Consider the potential threshold ε^* defined by (3) and let ε^{Max} be defined by (7). Then, $\varepsilon^* = \varepsilon^{\text{Max}}$. If, in addition, $P(x)$ has a unique root $\bar{x} \in (0,1]$, then $\bar{\varepsilon}^{\text{MAP}} = \varepsilon(\bar{x})$ is an upper bound on the MAP threshold and $\varepsilon^* = \bar{\varepsilon}^{\text{MAP}}$.

Proof: Omitted due to similarity with Lem. 6. ■

Corollary 3: Consider the SC ensemble defined in Section III-A. If $\varepsilon < \varepsilon^*$ and $w > K_{f,g}/\Delta E(\varepsilon)$, then Theorem 1 shows that the SC DE recursion converges to the zero vector.

IV. CONCLUSIONS

A new theorem is presented that provides a simple proof of threshold saturation for many scalar DE recursions. The conditions of the theorem are verified for the density-evolution (DE) equations of irregular LDPC codes on the BEC, a class of generalized LDPC codes, and the joint iterative decoding of some intersymbol-interference channels with erasure noise. Therefore, threshold saturation is now proved for these cases. Moreover, we believe this approach opens the door to threshold-saturation proofs for many more general spatially-coupled systems.
